## MA 114 Worksheet \#17: Average value of a function

1. Write down the equation for the average value of an integrable function $f(x)$ on $[a, b]$.
2. Find the average value of the following functions over the given interval.
(a) $f(x)=x^{3},[0,4]$
(e) $f(x)=\frac{\sin (\pi / x)}{x^{2}},[1,2]$
(b) $f(x)=x^{3},[-1,1]$
(f) $f(x)=e^{-n x},[-1,1]$
(c) $f(x)=\cos (x),\left[0, \frac{\pi}{6}\right]$
(g) $f(x)=2 x^{3}-6 x^{2},[-1,3]$
(d) $f(x)=\frac{1}{x^{2}+1},[-1,1]$
(h) $f(x)=x^{n}$ for $n \geq 0,[0,1]$
3. In a certain city the temperature (in ${ }^{\circ} F$ ) $t$ hours after 9 am was modeled by the function $T(t)=50+14 \sin \frac{\pi t}{12}$. Find the average temperature during the period from 9 am to 9 pm.
4. The velocity $v$ of blood that flows in a blood vessel with radius $R$ and length $l$ at a distance $r$ from the central axis is

$$
v(r)=\frac{P}{4 \eta l}\left(R^{2}-r^{2}\right)
$$

where $P$ is the pressure difference between the ends of the vessel and $\eta$ is the viscosity of the blood. Find the average velocity (with respect to $r$ ) over the interval $0<r<R$. Compare the average velocity with the maximum velocity.
5. Breathing is cyclic and a full respiratory cycle from the beginning of inhalation to the end of exhalation takes about 5 s . The maximum rate of air flow into the lungs is about $0.5 \mathrm{~L} / \mathrm{s}$. This explains, in part, why the function $f(t)=\frac{1}{2} \sin (2 \pi t / 5)$ has often been used to model the rate of air flow into the lungs. Use this model to find the volume of inhaled air in the lungs at time $t$. Then use this new function to compute the average volume of inhaled air in the lungs in one respiratory cycle.
